

Case Study: Contract Clause Tracker

Background

Legal teams need to track specific clauses across multiple contracts. Your task is to build a small web application that helps users to track and maintain which contracts contain which types of clauses. For simplicity, we assume a legal clause is always represented by a single sentence.

Core Requirements

Build an application where users can:

1. **Upload contracts** - plain text or markdown files
2. **View document and label clause types** (e.g., "Limitation of Liability", "Termination for Convenience", "Non-Compete") - user should be able to label single sentences with clause type
3. **View a dashboard with document list** - with options for search, filter and grouping

Technical Requirements

- **Backend:** Python (Flask or FastAPI preferred)
- **Frontend:** Angular
- **Database:** SQLite or PostgreSQL
- **Containerization:** Provide a `Dockerfile` and `docker-compose.yml` so we can run it with `docker-compose up`

What We're Looking For

- Clean, maintainable code structure
- A working API with reasonable endpoint design
- An intuitive UI which supports the user with labeling clause types
- Database schema that fits the domain

Bonus Points (optional)

- Tests for critical paths
- Brief notes on how you'd extend this (scaling, AI features, etc.)

Deliverables

- GitHub repository (public or invite us)
- README explaining setup and your design decisions

Time Expectation

3–4 hours maximum. We're looking for a UX which is intuitive, self-explaining and appealing. We want to see how you think, structure code, and make decisions. The backend code should be minimal.

We'll extend this together in a pair programming session (by adding an automatic labeling step).
